OBJECTIVES
To describe the use of a polypropylene mesh implant in a cone-shaped plug design, previously described in human medicine, as a novel canine perineal herniorrhaphy technique in cases of severe pelvic diaphragm muscle atrophy.

METHODS
Medical records from a small animal primary care centre were reviewed from 2013 to 2016. Three cases of canine perineal herniorrhaphy treated with a polypropylene mesh in a cone-shaped plug design were included.

Case 1: A 10-year-old, neutered male, Shih Tzu presented with a history of dyschezia, tenesmus and constipation for 2 months.

Case 2: A 12-year-old, entire male, Yorkshire Terrier presented with a history of dyschezia and tenesmus for 16 months.

Case 3: An 11-year-old, entire male, German Shepherd presented with a history of dyschezia and tenesmus for 11 months.

A polypropylene flat mesh (15cmx15cm) rolled into a pointed cone-shaped plug was placed into the perineal defect in each case. A simple interrupted suture pattern with absorbable monofilament polydioxanone was used between the base of the cone and the muscles involved.

RESULTS
Neither recurrence nor surgical site infection have been reported to date. However, post-operative tenesmus was described in one patient (case 3) which resolved spontaneously. No other concerns were recorded.

STATEMENT
The authors believe the use of a polypropylene mesh implant in a three dimensional design provides extra mechanical strengthening and stabilization of the pelvic diaphragm. Thus, this advanced surgical alternative tension-free herniorrhaphy can be a suitable technique in cases of severe muscle atrophy and warrants further investigation.

CONFLICTS OF INTEREST
The authors declare no conflict of interest.

Uterine remnant adenocarcinoma in a bitch with ovarian remnants: a case report

OBJECTIVES
To describe the first reported case of uterine stump adenocarcinoma in a dog with ovarian remnants and its successful surgical treatment.

METHODS
A 3-year-old, female dog was presented with sanguineous vaginal discharge, 1.5 year after spaying. Physical examination and abdominal diagnostic imaging, both radiologic and ultrasonographic, revealed an irregular mass in the caudal abdomen. Blood tests were within normal limits. High serum progesterone concentration confirmed diestrus and presence of functional ovarian remnants, raising suspicion of uterine stump pyometra or enlargement. Given the results of the aforementioned examinations and the dog’s clinical status, the dog was directly prepared for surgery. During laparotomy both remnant ovaries and a large, hard, encapsulated mass at the uterine body remnant were excised after meticulous tissue separation due to extended symphysis with the adjacent organs.
